

Otosclerosis

Otosclerosis

This is an autosomal dominant condition of variable penetrance in which excess bone is laid down around the footplate of the stapes, impeding mobility of the stapes and resulting in a conductive hearing loss (Figure 51.23). A diagnosis should be suspected in any patient with a conductive hearing loss and a normal tympanic membrane. The treatment options are simple reassurance, a conventional hearing aid, a stapedotomy operation or bone conduction hearing aid (Figure 51.24).
