

Proximal femoral fractures

Proximal femoral fractures

The blood supply to the femoral head is a prime consideration in treating femoral neck fractures. The blood supply comes via the hip capsule and although vascular anatomy is variable - it is chiefly through the medial and lateral branches of the deep circumflex femoral artery in addition to the occasionally - redundant artery of the ligamentum teres (a branch of the obturator artery). The joint capsule anteriorly inserts along the intertrochanteric line and posteriorly half-way along the femoral neck. Fractures proximal to the hip capsule are intracapsular and those distal to the capsule are extracapsular fractures. Proximal femoral fractures
