

Temperature management

Temperature management

When undergoing burn assessment and fluid resuscitation it is vital that the patient maintains an adequate core temperature. A key function of skin is thermoregulation and in large burns this is severely impacted. Hypothermia is a component of the 'lethal triad of trauma', which includes acidosis and coagulopathy; the combination of all three significantly increases mortality. Measures to counteract hypothermia include infusing warmed fluids, external warmers such as the 'Bair Hugger' and increasing the ambient room temperature in the emergency department/assessment room.
